Optimizing the Performance of Multi-threaded Linear Algebra Libraries, a Task Granularity based Approach

Scientific Computing Around Louisiana (SCALA)

Shahrzad Shirzad, Dr. Hartmut Kaiser Feburary 8, 2020

Louisiana State University

Objective

A compile-time and runtime solution to optimize the performance of a linear algebra library based on

- Machine architecture
- Number of cores to run the program on
- Expression to be evaluated
 - Type of operations
 - Number of matrices involved
 - Matrix sizes

Introduction

Introduction

- Current programming models would not be able to keep up with the advances toward exascale computing
 - More complex machine architectures, deeper memory hierarchies, heterogeneous nodes, complicated networks
- AMT(Asynchronous Many-Task) model and runtime systems
 - Examples: HPX, Charm++, Legion

Introduction

- Performance of HPC applications heavily rely on the linear algebra library they are using.
- Linear algebra libraries
 - BLAS(Basic Linear Algebra Subprograms) are the fundamental routines for basic vector and matrix operations.
 - Examples: ScaLAPACK, ATLAS, SPIRAL
- Our motivation:
 - Phylanx, a platform to run your python code in parallel and distributed with machine learning as the target application.

Background

Background: HPX

- HPX is a general purpose C++ runtime system for parallel and distributed applications of any scale.
- Fine-grained parallelism instead of heavyweight threads.
- Four major factors for performance degradation: SLOW
 - Starvation
 - Latency
 - Overheads
 - Waiting for contention resolution

Background: Blaze C++ Library

Blaze is a high performance C++ linear algebra library based on Smart Expression Templates.

- Expression Templates:
 - Creates a parse tree of the expression at compile time and postpone the actual evaluation to when the expression is assigned to a target
- Smart:
 - Integration with highly optimized compute kernels
 - Selecting optimal evaluation method automatically for compound expressions

Background: Blaze, Parallelization

Depending on the operation and the size of operands, the assignment could be parallelized through four different backends

• HPX, OpenMP, C++ threads, Boost

In the current implementation, the work is equally divided between the cores at compile time.

Parallel for loop

Figure 1: An example of how C=A+B is performed in parallel in Blaze with 4 cores

Background: Task Granularity

Grain size: The amount of work performed by one task

- What causes performance degradation?
 - Overheads
 - Starvation

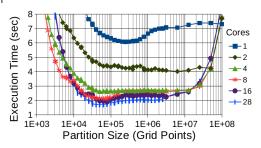

Figure 2: The effect of task size on execution time for Stencil application¹

¹Grubel, Patricia, et al. "The performance implication of task size for applications on the hpx runtime system." 2015 IEEE International Conference on Cluster Computing. IEEE, 2015.

Method

Method: Objective

Dynamically divide the work among the cores based on number of cores, matrix size, complexity of the operation, machine architecture. For this purpose two parameters have been introduced:

- block_size: at each loop iteration the assignment is performed on one block
- chunk_size: the number of loop iterations included in one task

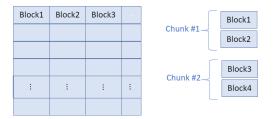

Figure 3: An example of blocking a matrix and creating chunks for chunk_size = 2

Method: Data Collection

• Starting from DMATDMATADD benchmark: C = A + B

Category	Configuration
Matrix sizes	200, 230, 264, 300, 396, 455, 523, 600, 690, 793, 912, 1048, 1200, 1380, 1587
Number of cores	1, 2, 3, 4, 5, 6, 7, 8
Number of rows in the block	4, 8, 12, 16, 20, 32
Number of columns in the block	64, 128, 256, 512, 1024
Chunk size	Between 1 and total number of blocks (logarithmic increase)

Table 1: List of different values used for each variable for running the DMATDMATADD benchmark

Method: Data Analysis

 For simplicity we look at each matrix size individually, one number of core at a time

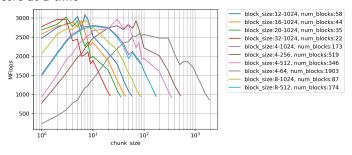

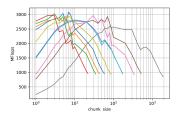

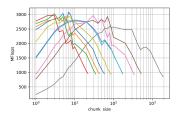

Figure 4: The results obtained from running DMATDMATADD benchmark for matrix sizes 690×690 with different combinations of block size and chunk size on 4 cores

Method: Observation

- For each selected block size, there is a range of chunk sizes that gives us the best performance.
- Except for some uncommon cases, no matter which block size we choose, we are able to achieve the maximum performance if we select the right chunk size.

Method: Observation

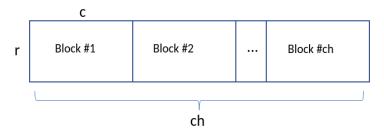

- For each selected block size, there is a range of chunk sizes that gives us the best performance.
- Except for some uncommon cases, no matter which block size we choose, we are able to achieve the maximum performance if we select the right chunk size.
- Instead of looking at block size and chunk size individually, look at grain size.

Method: Throughput vs. Grain Size

Grain size: The number of floating point operations performed by one thread

- Grain size represents the complexity of the expression
- For DMATDMATADD, with $block_size = r \times c$ and $chunk_size = ch$ $Grain_size = r \times c \times ch$

Method: Throughput vs. Grain Size

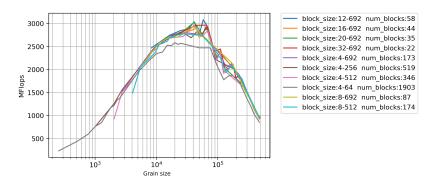

Figure 5: The results obtained from running DMATDMATADD benchmark through Blazemark for matrix size 690×690 on 4 cores.

Method: Throughput vs. Grain Size

The range of grain size for maximum performance

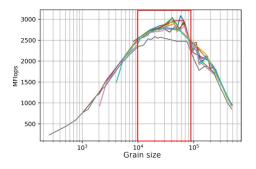

Figure 6: The results obtained from running DMATDMATADD benchmark through Blazemark for matrix size 690×690 on 4 cores.

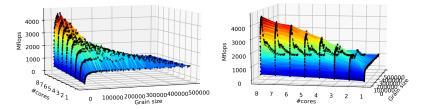

Figure 7: The results obtained from running DMATDMATADD benchmark through Blazemark for matrix size 690×690 based on grain size and number of cores.

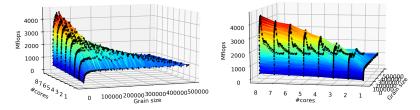

Figure 7: The results obtained from running DMATDMATADD benchmark through Blazemark for matrix size 690×690 based on grain size and number of cores.

Can we model the relationship between the **throughput** and the **grain** size and the **number of cores**?

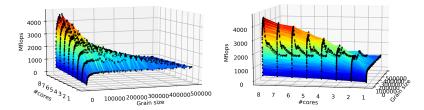

Figure 7: The results obtained from running DMATDMATADD benchmark through Blazemark for matrix size 690×690 based on grain size and number of cores.

Can we model the relationship between the **throughput** and the **grain** size and the **number of cores**?

• First we try to model the relationship between throughput and grain size.

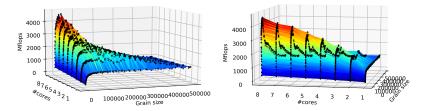

Figure 7: The results obtained from running DMATDMATADD benchmark through Blazemark for matrix size 690×690 based on grain size and number of cores.

Can we model the relationship between the **throughput** and the **grain** size and the **number of cores**?

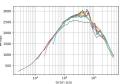

- First we try to model the relationship between throughput and grain size.
 - Polynomial Model

Method: Polynomial Model

In order to simplify the process and eliminate the effect of different possible factors, we started with limiting the problem to a fixed matrix size.

 Used a second order polynomial to model the relationship between the throughput and the grain size when number of cores is fixed.

$$P = ag^2 + bg + c$$

Divide the data into training(60%) and test(40%)

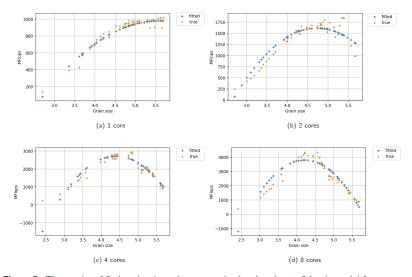

Figure 8: The results of fitting the throughput vs grain size data into a 2d polynomial for DMATDMATADD benchmark for matrix size 690×690 with different number of cores on the test data.

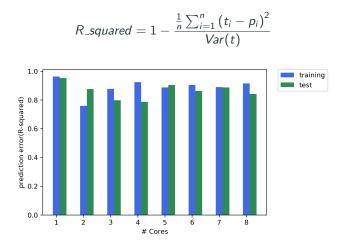

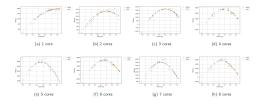

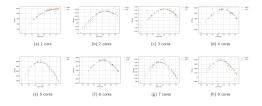

Figure 9: The training and test error for fitting data obtained from the <code>DMATDMATADD</code> benchmark for matrix size 690×690 against different number of cores cores.

• We have developed a model for each number of cores:1, 2,.., 8 $P = ag^2 + bg + c$

- We have developed a model for each number of cores:1, 2,.., 8 $P = ag^2 + bg + c$
- Can we somehow integrate number of cores into the model?

• For $P = ag^2 + bg + c$, how do a, b, and c change with the number of cores?

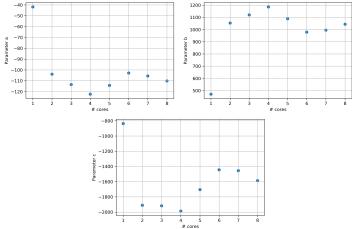

Figure 10: The parameters of the polynomial fit from the DMATDMATADD benchmark for matrix size 1587×1587 against different number of cores.

• Model the relationship with a 3rd degree polynomial

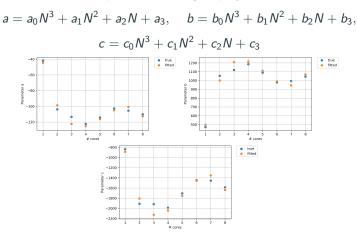

Figure 11: Fitting the parameters of the polynomial function with a 3rd degree polynomial from the DMATDMATADD benchmark for matrix size 1587×1587 against different number of cores.

The final model:

$$P = \sum_{i=0}^{2} \sum_{j=0}^{3} a_{ij} g^{i} N^{j}$$

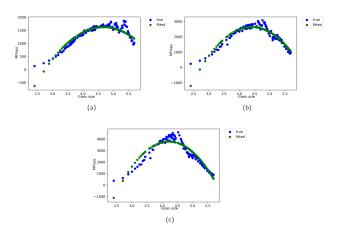

Figure 12: matrix size 690×690 for (a) 2 core. (b) 4 cores. (c) 8 cores.

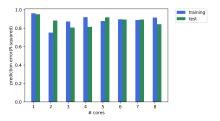

Figure 13: All the data points are included in calculation of error, R_squared error.

Method: Finding the Grain Size Range for Maximum Performance

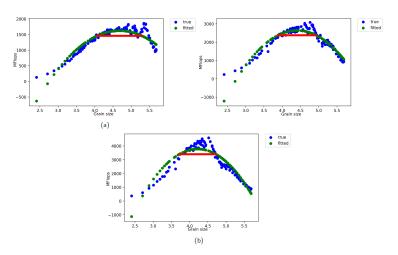

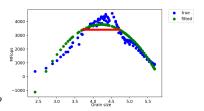

Figure 14: The range of grain size (shown as the red line) that leads to a performance within 10% of the maximum performance for (a) 2 cores, (b) 4 cores and (b) 8 cores.

Method: Finding the Grain Size Range for Maximum Performance

How do we use the calculated range?

- ullet Select a reasonable block size, e.g. 4 imes 512
- Find the range of chunk size that results in the calculated range of grain size, Grain_size=r × c × ch

Method: Finding the Grain Size Range for Maximum Performance

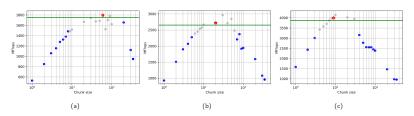

Figure 15: matrix size 690×690 with block size of 4×512 on (a) 2 cores, (b) 4 cores, and (c) 8 cores.

Method: Polynomial Model, Wrap up

Strength:

• Simple model, can easily find the maximum.

Weakness:

• It is not physical.

Setup: Blazemark

Blazemark is a benchmark suite provided by Blaze to compare the performance of Blaze with other linear algebra libraries.

Figure 16: An example of results obtained from Blazemark

Setup: Configuration

Category	Specification
CPU	2 x Intel(R) Xeon(R) CPU E5-2450 0 @ 2.10GHz
RAM	48 GB
Number of Cores	16
Hyperthreading	Off

Table 2: Specifications of the Marvin node from Rostam cluster at CCT.

Library	Version
HPX	1.3.0
Blaze	3.5

Table 3: Specifications of the libraries used to run our experiments.

Our Contributions

- To our knowledge, there has not been a work to create a 3D model of the throughput, grain size, and number of cores.
- We are proposing a method to apply the developed model to a linear algebra library, in a way specific to our application, and the machine architecture.

Future Work

Future Work

- Generalizing the current model to different matrix sizes
- Looking into more complex expressions
- Finding an analytical model to explain the observed behavior between execution time, grain size, and number of cores.

Thank you!
